WBMP

WBMP stands for **Wireless Bitmap**.

WML cards can contain images. In the early days, WAP-enabled wireless devices only supported the Wireless Bitmap **(WBMP)** image format. **WBMP** images can only contain two colors: black and white. Also, **WBMP** is not a compressible format, since the processor of wireless devices in the old days did not have enough computation power and decompression would result in a long delay. The file extension and the MIME type of **WBMP** are ".wbmp" and "image/vnd.wap.wbmp" respectively.

To draw **WBMP** images, a **WBMP** image editor is needed. The Nokia Mobile Internet Toolkit comes with a **WBMP** image editor that you can use. Besides drawing **WBMP** images, you can use it to convert other image formats to **WBMP**. Just open a GIF or JPG image file with the editor and it will be converted automatically. Free tools such as ImageMagick can also do such kind of thing. However, remember that **WBMP** images can only contain black and white colors, which means there will have detail loss during the conversion of a colorful image to the **WBMP** format.

A WML browser can display color images if the image format used is supported by the wireless device. Currently, most mobile phone models on the market have color screens and support color images. Commonly supported image formats are GIF 87a, GIF 89a (animated GIF), JPG and PNG. Note that the image formats supported are device-specific. Some wireless devices can only support a subset of the above image formats.
