CutePress WordPress blog manager - app showcase

CutePress app allows users to manage pages, posts, comments and media items on WordPress blogs. This article explains the main elements of the app design.

Introduction

CutePress allows user manage pages, posts, comments and media items on WordPress blogs. It needs an active GPRS connection or Wi-fi (on Wif-fi enabled devices) to access Internet.

Cutepress is a QML version of WordPress for Nokia app http://nokia.wordpress.org/ with some additional features.

It supports WordPress 2.7 or higher(WordPress.com or self-hosted).

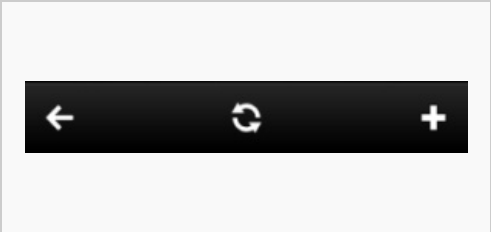
CutePress is built using codebase of official WordPress for Nokia app and **will be merged with the original version in the coming future**.

It is built using Qt Quick components providing various enhancement to WordPress app.

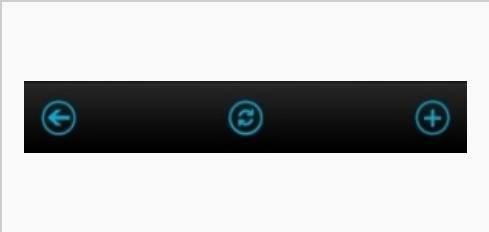
CutePress is a Nokia Conversation recommended app and it has nearly 5k downloads on Nokia store. With v1.2.0, it has been also translated for Turkish language with the help of MeeGo Turkey

Qt-Quick UI & Design Guidelines Compliance

As CutePress is built using QtQuick 1.0 components it complies to almost every Symbian guideline. It uses a vast number of components ranging from `PageStack` to `Animation` classes. For compliance of icon guidelines, default Symbian toolbar icons are added to v1.2.0.



Belle style icons



Metro icons

Logical and consistent navigation structure
CutePress provide a consistent navigation for easy operation with every view having a back button to traverse to previous view and apart from blogs list view which is the initial page for the application and clicking back button on this view closes the application.

CutePress tries to use best possible icons for representing respective functionality and for preventing any confusion is user's mind it also have help view where a table of icons and their functionality is shown.

App icon consistent with Symbian style

CutePress app icon attached with the article is clearly having a consistent design with Symbian style.

Correct use of the components

CutePress is based on QtQuick 1.0 and QtQuick components for Symbian & MeeGo for corresponding platforms. Therefore, it is tried best to use QML components properly for consistent functioning with a number of built in and custom created components.

Non-threatening interface - don't ask the user for confirmation or passwords unless necessary

To prevent user for logging in again & again on each run, blog details are stored in a file. This way CutePres asks blog admins to login only once for adding a blog.

Good use of screen real estate

CutePress tries to provide maximum details in minimum possible way. To denote information about list items in pages & posts list view, color coding is used. Color codes for different publish status are defined in help view to prevent any confusion.

Utilising the toolbar where appropriate.

CutePress tries to maximize utilization of toolbar.

Problems faced & solutions implemented

A number of problems were faced during development of CutePress. Some were related to porting QWidget UI to QML equivalent while some were related Symbian platform constraint.

Caching Image Thumbnails for smooth working of UI

For selecting images form gallery to upload on the blog, it was important to show thumbnails for images for easy use. As it was difficult to access Symbian thumbnail cache, application tries to built its own. And when image selection view is opened by user, it initially loads only 36 images. Subsequent images are loaded whenever user reaches at the end of list. Code an be found here:
https://code.google.com/p/cutepress/source/browse/src/worker.cpp

https://code.google.com/p/cutepress/source/browse/src/thumbnailthread.cpp

https://code.google.com/p/cutepress/source/browse/qml/symbian/NewMediaPage.qml

List Delegate for Post, Page, Comments

To show maximum possible information about a post or a page or a comment custom list delegate are used. Colored code s are used to represent status of an item.

Problem with HTML text and TextField in QtQuick 1.0 & using it with a Flickable item

TextFiled in Symbian QtQuick 1.0 can't handle HTML text properly. This problem still persits in the application, however MeeGo version with QtQuick 1.1 works fine.

Another problem was using TextField element with a Flickable item. In this case TextField's height is set to its implicitHeight and width is set to slighly lesser than its parent item.This way TextField can expanded vertically as needed and to scroll down on the page.
