Inside Qt meta Object

Introduction

In this article we will discuss how and why we use **meta-object** in Qt.

The word **meta** indicates that the word prefixed is about itself. So a **meta-object** is an object describing the object. QT Meta-Object Compiler, moc, is the program that handles Qt's C++ extensions.The moc reads C++ source files, if it finds one or more class declarations that contain the `Q_OBJECT` macro, it produces another C++ source file which contains the meta object code for those classes and those are automatically included by build system.

QMetaObject Class

A **meta-object** contains information about a class that inherits `QObject`, e.g. class name, super class name, properties, signals and slots. Every `QObject` subclass that contains the `Q_OBJECT` macro will have a meta-object. Following code declares **MyQTClass** which has a property declared by `Q_PROPERTY` macro. This will allow us to update the property in several ways.

```
 class MyQTClass : public QObject
 {
     Q_OBJECT
     Q_PROPERTY(int Myage READ Age WRITE setAge)
 public:
  MyQTClass();
  ~MyQTClass();
  void SomeFunction();
  int Age();
  void setAge(int aAge);
 private:
     QString myName;
     int Myage;
     bool abool;
 };

// test code
     MyQTClass *myinstance = new MyQTClass;
     QObject *object = myinstance;

     myinstance->setAge(100); // using setter function
     myinstance->setProperty("Myage", 100); //using property
     int retage =myinstance->Age(); // retage should be 100

    //Setting property
     QVariant v(123);
     bool b = object->setProperty("Myage", v); // b is true since we have a Myage
property
     b = object->setProperty("aVariable", v); // b is not true

     QVariant test = object->property("Myage");
     b = test.isValid(); // b is true
     QVariant wrong = object->property("aVariabdfhdfgle");
     b = wrong.isValid(); // b is not true
```

```
     const QMetaObject *metaobject = object->metaObject();
     QString classname(metaobject->className()); // classname shoudl be "MyQTClass"

     int count = metaobject->propertyCount(); // number of Property
     for (int i=0; i<count; ++i)
      {
         QMetaProperty metaproperty = metaobject->property(i);
         const char *name = metaproperty.name(); // property name should come from
MyQTClass + QObject
         QString propertyName(name);
     }
```

In the above code,at the very top of the class declaration we find the `Q_OBJECT` macro. It is important that this macro appears first in the body of the class declaration because it marks the class as a class that needs a **meta-object**. In the case of Qt, **meta-objects** are instances of the class. It means that the above code goes into a file called `MyQTClass.h`. The implementation goes into `MyQTClass.cpp`, and the moc generates another C++ file from the header file called `moc_MyQTClass.cpp`. The contents from the generated file can change between Qt versions.

Example Applications
